## **Cheat Sheet: Python Data Structures Part-2**

## **Dictionaries**

```
Package/Method Description
                                                                 Code Example
                    A dictionary is
                    a built-in data
                                    Example:
                    type that
                    represents a
                                      1. 1
                    collection of
Creating a
                    key-value
Dictionary
                                       1. dict_name = {} #Creates an empty dictionary
                    pairs.
                                      2. person = { "name": "John", "age": 30, "city": "New York"}
                    Dictionaries
                                     Copied!
                    are enclosed
                    in curly
                    braces {}.
                                    Syntax:
                                      1. 1
                                      1. Value = dict_name["key_name"]
                    You can
                    access the
                                    Copied!
                    values in a
                                    Example:
Accessing Values
                    dictionary
                    using their
                    corresponding
                                      2. 2
                    keys.
                                       1. name = person["name"]
                                      2. age = person["age"]
                                    Copied!
                                    Syntax:
                    Inserts a new
                    key-value pair
                                       1. dict name[key] = value
                    into the
                                     Copied!
                    dictionary. If
                    the key
                    already exists, Example:
Add or modify
                    the value will
                    be updated;
                    otherwise, a

    person["Country"] = "USA" # A new entry will be created.

                    new entry is
                                      2. person["city"] = "Chicago" # Update the existing value for the same key
                    created.
                                     Copied!
                                    Syntax:
                    Removes the
                    specified key-

    del dict_name[key]

                    value pair
                                    Copied!
                    from the
del
                    dictionary.
                                    Example:
                    Raises a
                    KeyError if the
                    key does not
                                      1. del person["Country"]
                    exist.
                                     Copied!
```

1 of 5

```
Syntax:
                    The \ {\tt update()}
                                       1. 1
                    method
                    merges the
                                       1. dict_name.update({key: value})
                    provided
                                     Copied!
                    dictionary
update()
                    into the
                                    Example:
                    existing
                    dictionary,
                                       1. 1
                    adding or
                                       1. person.update({"Profession": "Doctor"})
                    updating key-
                    value pairs.
                                     Copied!
                    The clear()
                                    Syntax:
                    method
                    empties the
                                       1. 1
                    dictionary,

    dict_name.clear()

                    removing all
                    key-value
                                     Copied!
                    pairs within
clear()
                    it. After this
                                    Example:
                    operation, the
                    dictionary is
                    still

    grades.clear()

                    accessible
                                     Copied!
                    and can be
                    used further.
                    You can check Example:
                    for the
                                       1. 1
                    existence of a
                                       2. 2
key existence
                    key in a
                                       1. if "name" in person:
                    dictionary
                                              print("Name exists in the dictionary.")
                                       2.
                    using the in
                                     Copied!
                    keyword
                    Creates a
                                    Syntax:
                    shallow copy
                    of the
                    dictionary.
                                       1. new_dict = dict_name.copy()
                    The new
                                     Copied!
                    dictionary
                    contains the
                                    Example:
copy()
                    same key-
                    value pairs as
                                       1. 1
                    the original,
                    but they
                                       1. new_person = person.copy()
                    remain
                                       2. new person = dict(person) # another way to create a copy of dictionary
                    distinct
                                     Copied!
                    objects in
                    memory.
                                    Syntax:
                    Retrieves all
                    keys from the
                                       1. keys_list = list(dict_name.keys())
                    dictionary and
                    converts them Copied!
                    into a list.
keys()
                    Useful for
                                    Example:
                    iterating or
                                       1. 1
                    processing
                    keys using list
                                       1. person_keys = list(person.keys())
                    methods.
                                     Copied!
```

**Code Example** 

**Description** 

## **Sets**

Package/Method

i ackage/Memou	Description	Code Liampie
		Syntax:
	Elements can be added to a set using the `add()` method. Duplicates are automatically removed, as sets only store unique values.	1. 1
		<pre>1. set_name.add(element)</pre>
		Copied!
		Example:
		1. 1
		<ol> <li>fruits.add("mango")</li> </ol>
		Copied!
clear()	The `clear()` method removes all elements from the set, resulting in an empty set. It updates the set inplace.	Syntax:
		1. 1
		<pre>1. set_name.clear()</pre>
		Copied!
		Example:
		1. 1
		<pre>1. fruits.clear()</pre>
		Copied!
		Syntax:
copy()	The `copy()` method creates a shallow copy of the set. Any modifications to the copy won't affect the original set.	1. 1
		<pre>1. new_set = set_name.copy()</pre>
		Copied!
		Example:

3 of 5 14/10/23, 16:46

```
1. 1
                                                            1. new_fruits = fruits.copy()
                                                          Copied!
                                                         Example:
                   A set is an unordered collection of
                                                            2. 2
                   unique elements. Sets are enclosed
                   Defining Sets
                                                            1. empty set = set() #Creating an Empty
                   useful for storing distinct values
                                                            2. Set fruits = {"apple", "banana", "orange"}
                   and performing set operations.
                                                          Copied!
                                                         Syntax:

    set name.discard(element)

                   Use the 'discard()' method to
                                                          Copied!
                   remove a specific element from the
discard()
                   set. Ignores if the element is not
                                                         Example:
                   found.
                                                            1. 1
                                                            1. fruits.discard("apple")
                                                          Copied!
                                                         Syntax:
                                                            1. 1
                                                            1. is_subset = set1.issubset(set2)
                   The `issubset()` method checks if
                   the current set is a subset of
                                                          Copied!
                   another set. It returns True if all
issubset()
                   elements of the current set are
                                                         Example:
                   present in the other set, otherwise
                   False.
                                                            1. is_subset = fruits.issubset(colors)
                                                          Copied!
                                                         Syntax:
                   The `issuperset()` method checks if is_superset = set1.issuperset(set2)
                   the current set is a superset of
                                                         Example:
                   another set. It returns True if all
issuperset()
                   elements of the other set are
                   present in the current set,
                                                            1. is_superset = colors.issuperset(fruits)
                   otherwise False.
                                                         Copied!
                                                         Syntax:
                                                            1. 1
                                                            1. removed_element = set_name.pop()
                   The 'pop()' method removes and
                   returns an arbitrary element from
                                                          Copied!
                   the set. It raises a `KeyError` if the
pop()
                   set is empty. Use this method to
                                                         Example:
                   remove elements when the order
                                                            1. 1
                   doesn't matter.
                                                            1. removed_fruit = fruits.pop()
                                                          Copied!
                   Use the `remove()` method to
                                                         Syntax:
remove()
                   remove a specific element from the
                                                            1. 1
```

1. set\_name.remove(element) Copied! Example: set. Raises a `KeyError` if the element is not found. 1. 1 fruits.remove("banana") Copied! Syntax: 1. 1 2. 2 3. 3 4.4 1. union\_set = set1.union(set2) 2. intersection set = set1.intersection(set2) 3. difference set = set1.difference(set2) 4. sym\_diff\_set = set1.symmetric\_difference(set2) Perform various operations on sets: Copied! `union`, `intersection`, `difference`, `symmetric Example: difference`. 1. 1 2. 2 3. 3 4. 4 1. combined = fruits.union(colors) 2. common = fruits.intersection(colors) 3. unique\_to\_fruits = fruits.difference(colors)
4. sym\_diff = fruits.symmetric\_difference(colors) Copied! Syntax: 1. set\_name.update(iterable) The `update()` method adds Copied! elements from another iterable into

update()

**Set Operations** 

the set. It maintains the uniqueness Example: of elements.

1. fruits.update(["kiwi", "grape"])

Copied!
